TOXIC

BLUE-GREEN

algae

BLOOMS

If you . . .

- Are a lake resident
- Enjoy lake activities such as swimming, fishing, boating
- Graze your livestock near a lake or pond
- Are a veterinarian

. . . you may be able to help prevent a health threat to people and animals from toxic blue-green algae blooms.

In their toxic form, blue-green algae can kill pets, waterfowl, and other animals. They can also cause serious illness in humans.

You can help by:

- Learning how to identify and avoid contact with a bloom.
- Reporting algae blooms to your local health department or the Washington State Department of Ecology.
- Decreasing excessive amounts of nitrogen and phosphorus in lakes and streams.

What is a blue-green algae bloom?

Blue-green algae, or cyanobacteria, reproduce rapidly in fresh water when the amount of sunlight, temperature, and nutrients are adequate. Within a few days a “clear” lake, pond, or ditch can become cloudy with algae growth. This is called a bloom. Blue-green blooms usually float to the surface and can be several inches thick near the shoreline.

A blue-green algae bloom:

- Often looks like green paint floating on the water.
- Is made up of extremely small organisms that are hard to pick up or hold.
- Can be bright green, or bluish, brownish, or reddish green.
- Is most common in the summer and fall but can occur anytime.

Although blue-green blooms can create nuisance conditions and undesirable water quality, most blue-green blooms are not toxic.

What is a toxic bloom?

Some blue-green algae produce toxins or poisons. Eventually the toxins break down and are destroyed naturally. Ingesting the algae while they are still poisonous can cause serious illness. Residential drinking water taken from a lake may be affected.

Signs of a toxic bloom may include:

- Large numbers of dead fish, waterfowl, or other animals.
- Sudden, unexplained sickness or death of a cat or dog, especially if it has algae on its mouth, legs, or feet.
- Skin rashes on humans after being in the water.

What if I see a bloom?

As soon as you notice a bloom or possible signs of poisoning:

- Avoid all contact with water containing the algae.
- Keep pets and livestock away from the water.
- Call the environmental health section of your local health department or the Washington State Department of Ecology.

Laboratory tests of water samples can confirm whether or not a bloom is toxic.

What types of toxins are produced by cyanobacteria?

Several types of toxins may be produced, depending on the cyanobacteria genera.

- Neurotoxins target nerve synapses or axons in mammals. Symptoms of neurotoxins may include muscle cramps, twitching, paralysis, cardiac failure, or death in animals.
- Hepatotoxins target the liver in mammals. Symptoms of hepatotoxins may include nausea, vomiting, or acute liver failure.
- Other toxins include irritants that may affect the skin, GI tract, or any exposed tissue.

What happens if a test is positive for toxicity?

If a test shows that a bloom is toxic, county health officials will decide whether to close the lake for recreation, post notifications of potential health concerns, or wait for further testing.

Can testing ensure that all areas of the lake are safe?

No. Cyanobacterial blooms are known to be very patchy in nature. It is possible for higher cyanobacteria densities to be present in areas not surveyed, particularly along shorelines. Recreational users should avoid contact with water whenever surface concentrations of algae are evident or when the lake has an obvious green to blue-green appearance.

How is it determined when the water becomes safe once a bloom is reported?

Washington State Department of Health guidelines advise that a lake continue to be sampled and tested once a week for toxicity after toxin levels are above a certain concentration. Recreational use should be avoided until levels drop below recommended guidelines. Local health officials will decide when to re-open the lake.

Can I eat fish from cyanobacteria contaminated water?

Microcystins can accumulate in fish tissues, especially in the liver, kidneys and other organs. Exercise caution when considering consumption of fish caught in a water body where major cyanobacteria blooms occur. Before eating, remove the internal organs, which may contain more of the algae/toxin.

What can I do about it?

Algae blooms are likely to occur during sunny, calm weather when high concentrations of nutrients are present in the water. Two important nutrients algae require for growth are phosphorous and nitrogen. These are found in animal and human waste (sewage) and in fertilizers. Excessive amounts of nitrogen and phosphorus may lead to “nutrient loading” in a lake, which may eventually lead to an algae bloom.

To help decrease nutrient loading:

1. Maintain or restore native plants around lake shorelines and streams that feed the lake. Native wetland plants help filter water and do not require pesticides or fertilizers for maintenance.
2. Be cautious with lawn and plant fertilizers and pesticides. Do not over-water, overfertilize, or use more than the recommended amount of pesticides.
3. Use proper care and maintain your septic system. Damaged septic systems are a source of nutrient loading into nearby water. Have your system pumped and inspected every 3–4 years.
4. Prevent surface water runoff from agricultural and livestock areas. Do not allow livestock to drink or defecate in streams or lakes. Do not feed waterfowl.
5. Take steps to prevent erosion around construction and logging operations. Erosion can carry nutrient-rich soil into nearby lakes.

Contact With Blue-Green Algae Can Be Poisonous

- Blue-green algae can produce nerve toxins and liver toxins. Call your doctor or veterinarian right away if you or your pets or livestock have signs of poisoning.
- Signs of neurotoxin poisoning appear within 15–20 minutes after ingestion.
 - In animals, signs include weakness, staggering, difficulty breathing, convulsions, and death.
 - In people, signs may include numbness of the lips, tingling in fingers and toes, and dizziness.
- It may be hours or days before signs of liver poisoning appear. Liver toxins can cause abdominal pain, diarrhea and vomiting in humans and death in animals.

Dear Colleague,

The Washington State Department of Health (DOH) is pleased to provide camera-ready art for printing this educational material. To ensure that the original quality of the piece is maintained, please read and follow the instructions below and the specifications included for professional printing.

- **Use the latest version.** DOH materials are developed using the most current information available, are checked for clinical accuracy, and are field tested with the intended audience to ensure they are clear and readable. DOH programs make periodic revisions to educational materials, so please check this web site to be sure you have the latest version. DOH assumes no responsibility for the use of this material or for any errors or omissions.
- **Do not alter.** We are providing this artwork with the understanding that it will be printed without alterations and copies will be free to the public. Do not edit the text or use illustrations or photographs for other purposes without first contacting us. Please do not alter or remove the DOH logo, publication number or revision date. If you want to use a part of this publication for other purposes, contact the Office of Health Promotion first.
- **For quality reproduction:** Low resolution PDF files are intended for black and white or color desktop printers. They work best if you are making only one or two copies. High resolution PDF files are intended for reproducing large quantities and are set up for use by professional offset print shops. The high resolution files also include detailed printing specifications. Please match them as closely as possible and insist on the best possible quality for all reproductions.
